, STEPHEN TERENCE FARRELL, hereby declar			

- I am the applicant mentioned above;
- I have been authorised by the applicant to make this declaration and have knowledge of the facts herein stated in the capacity as Director of the applicant;
- the inventor of the abovementioned invention is the person named above and the applicant has acquired the right to apply
 by virtue of an assignment from the inventor;
- to the best of my knowledge and belief, if a patent is granted on the application, there will be no lawful ground for the revocation of the patent.
- 5. this is a convention application and the earliest application from which priority is claimed as set out above is the first application in a convention country in respect of the invention claimed in any of the claims; and
- 6. the partners and qualified staff of the firm of Botha, Farrell Inc Attorneys, are authorised, jointly and severally, with powers of substitution and revocation to represent the applicant in this application as from the date of lodging thereof and to be the address for service of the applicant while the application is pending and after a patent has been granted on the application.

SIGNED AT PRETORIA THIS 17th DAY OF MARCH 2003

STEPHEN TERENCE FARRELL FOR: BERNARD LIONEL GIEN SIGNATURE (no legalization necessary)

Capacity:

If the Applicant is a Company or firm the names of the person(s) signing the form and their capacity (e.g. Director, Mandatory, Secretary, Procurist) must be stated.

If the right to apply is not by virtue of an assignment from the Inventor(s) delete "an assignment from the Inventor(s)" in paragraph 3 and give details of acquisition of right.

For non-convention applications delete paragraph 5.

This form, if it does not accompany the application, should be filed within an extensible period of 6 months from the application date.

54	DOWN THE HOLE DRILL ASSEMBLY

DOWN-THE-HOLE DRILL ASSEMBLY

FIELD OF THE INVENTION

This invention relates to a down-the-hole drill assembly and more particularly to an assembly which eliminates the use of a foot valve tube.

BACKGROUND TO THE INVENTION

The common trend with valveless down the hole hammers is to have a drill bit with a replaceable foot valve tube protruding from the head of the bit at the striking face of the bit and piston. This foot valve tube extends into the bore of the piston and when the piston moves away from the bit the foot valve tube pulls out of the bore of the piston and exhaust from the bottom chamber takes place through the center of the foot valve tube to the atmosphere via the center bore of the bit.

While the piston is striking the bit, and the bore of the piston is engaged with the foot valve tube, the top chamber is exhausting through the bore of the piston through the center of the foot valve tube and out to the atmosphere via the bore of the bit. When the piston reciprocates away from the bit the same happens to the exhausting of the lifting chamber.

This replaceable foot valve tube has one end fixed in the body of the bit and the other end is a sliding fit into the bore of the piston. The outer diameter of the foot valve tube is limited as an increase in diameter of the foot valve tube reduces the lifting surface area of the piston. It will also weaken the walls of the piston and bit at its striking face. To increase the strength of the foot valve tube the walls have to be made thicker. This will cause a further restriction in the exhausting air of the hammer and will result in reducing the performance of the hammer. Another problem experienced is the frequent breakage of the foot valve tube. This results in down time for the driller as he has to pull the drill string out the hole, remove the bit from the hammer and replace the foot valve tube.

OBJECT OF THE INVENTION

It is an object of this invention to provide a down-the-hole drill assembly which avoids the use of a foot valve tube.

SUMMARY OF THE INVENTION

In accordance with this invention there is provided a down-the-hole drill bit assembly providing exhaust passages from the upper and lower chambers past the inner end of the bit and through the body of the bit to exit openings through the bit face.

The invention also provides for the bit to have openings extending transversely through the wall of the bit into a blind bore extending from the bit face.

Further features of this invention provide for a flushing air orifice through the closed end of the drill.

A still further feature of this invention provides a drill bit for the assembly above defined.

BRIEF DESCRIPTION OF THE DRAWINGS

These and other features of this invention will become apparent from the following description of embodiments, by example only, with reference to the accompanying drawings in which

FIG.1 is a longitudinal cross section through the assembly; and

FIGS.2 and 3 show alternative forms of drill bit.

DETAILED DESCRIPTION OF THE INVENTION

As illustrated the assembly (1) provides for lifting air to the lower chamber (11) of the piston (10) via the bore (9) of the piston (10) and the exhaust via the outside of the piston (10) and also via at least part of the outside of the bit (19) body. The exhaust air is then directed via porting (18) to the inside of the bit's drill face only because it is beneficial for flushing the drill cuttings out from underneath the bit face. The function of the hammer (1) is effective due to the fact that the compressed air flows directly through the bore (9) of the piston (10) with no deviation into the lower chamber (11) and causes the piston (10) to reciprocate faster thereby releasing more energy to the bit (19).

Operatively described, the down-the-hole drill bit (1) assembly has compressed air entering the hammer at (2) in the backhead (3). The flow of the compressed air opens the check valve (4) down against its spring bias and the air flows through check valve ports (5) down the air distributor (6) and out of ports (7). Pin (8) is disengaged from bore (9) of piston (10). The air flows down the piston bore (9) to pressurize lower chamber (11). The pressure acts on surface (12) to lift the piston (10) to start its upward stroke. During the upward stroke, pin (8) enters bore (9) to shut off the airflow to chamber (11). The piston (10) continues in its upward stroke and shoulder (13) of the piston (10) passes port (14) in the inner

sleeve (15) and the expanding air in lower chamber (11) exhausts through port (14) down cutout (16) through port (17) of the inner sleeve (15), through port (18) in the shank wall of the bit (19) and through (20) to the atmosphere. The piston (10) continues traveling upward with bore (9) shut off by pin (8). Shoulder (21) of the piston (10) passes shoulder (22) of the air distributor (6) and air flows from ports (7) via the bore (9) of the piston (10) into upper chamber (24). The pressure in chamber (24) now acts on surface area (25) and (26) to cause the piston (10) to travel downward towards the bit (19). During the piston's downward travel step (27) on the piston (10) passes cutout (28) in the bore of the wear sleeve (29) and the expanding air from chamber (24) exhausts down cutouts (30) on the piston (10) down through passage (31) through port (14) in the inner sleeve (15) down cutout (16) through ports (17) then (18) in the bit (19) and through (20) to the atmosphere.

When the bit (19) is lifted away from the rock face, the bit (19) will drop forward to be stopped by the bit retaining rings (33). The piston (10) will follow the bit (19) and ports (7) will be exposed to upper chamber (24). Air pressure acting on surfaces (25) and (26) exerts more force than the pressure acting on surface area (12) in lower chamber (11). The piston (10) will therefore remain inoperative. The airflow from upper chamber (24) follows the exhaust path down (30), (31) through port (14) down (16) and through (17), (18) and (20) to the atmosphere. Pressure in lower chamber (11) is released via cutout (34) on the bit head (19), through (18) and (20) to the atmosphere.

The assembly is robust and provides satisfactory operating surfaces on the piston and bit both for air pressure and striking force.

Fig. 2 shows an enlarged view of a bit wherein the passage (20A) is formed by drilling from the inner end of the bit and subsequently fitting a plug (35) to close the opening at the inner end of the bit (19). The lateral opening (18) is elongate

to provide easy flow of exhaust air from the assembly to flush the outer operative end of the bit (19).

Where desired the plug (35) can have an additional flushing air flow path (36) and may be made to be interchangeable with a solid plug.

Fig 3 shows a drill bit (37) which has no axial exhaust passage but where such passage is provided at (38) in the outer part of the bit (37). These passages (38) feed into passages (39) which extend through the face of the bit (37) to the atmosphere.

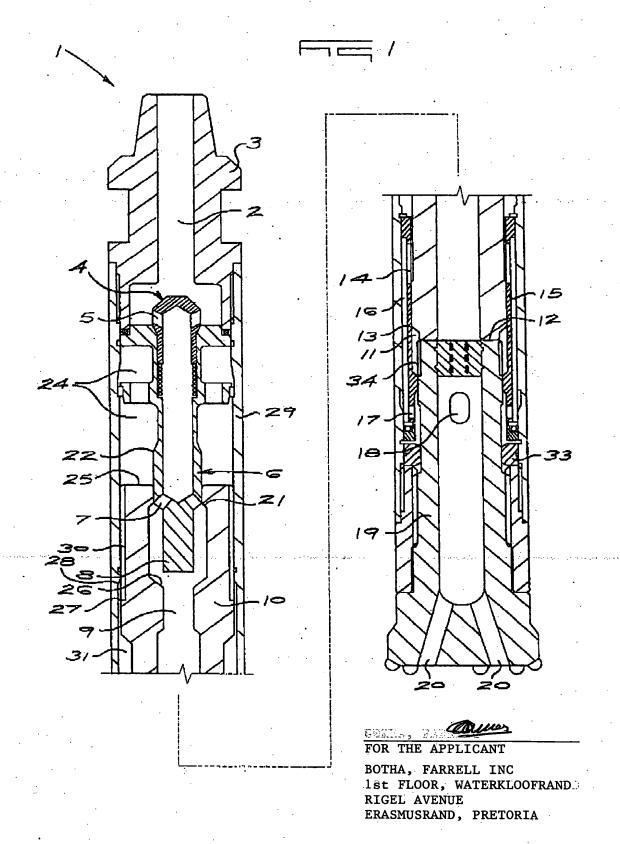

It will be appreciated that the exhaust air flow passages can take several different configurations. All of these will permit the foot valve tube to be dispensed with providing concomitant advantages to the assembly.
